

CSS FlexBox

It is used to layout the contents in 1D. When applied, all previous rules of display are discarded. For example: inline, block etc. are discarded.

Everything comes inside a container and flex property is applied to everything inside that flex.

```
<div class="container">
  <p></p>
  <li class='red'>Red</li>
  <li class='blue'>blue</li>
  <li class='green'>green</li>
</div>
```

```
<style>
  .container {
    display: flex;
    gap: 1rem;
    flex-direction: row;
  }

  .container -> * {
    flex-basis: 100px;
  }

  .red { order: 10}
</style>
```

Everything inside a container will come on one line and gap of 1rem will be applied between p and li elements.

display: flex	Takes the whole block.
display: inline-flex	Takes only the required space.
flex-direction: row	Everythings get aligned in one row and main axis is from left to right(->)
flex-direction: column	Everythings get aligned in one column and main axis is from top to bottom
flex-basis: 100px	Size of every element inside a container changes to 100px. It is done on the main axis.
	If it is row, then left to right and if column, then top to bottom.
	flex-basis is not applied on container whereas on children.
flex: 1	It is applied on children.

```
// Flex Layout
1. order: 0      It is applied on child. Child with highest value will move to the end.
                 red li will move to the end.
```

```
2. flex_wrap: nowrap  If li elements are unable to come in one line. They will just disappear and not move to next line.
   flex_wrap: wrap    Elements will move to next line.
```

```
3. justify_content  Values: flex_start, flex_end, center, space-between. It works on main axis.
```

```
4. align-items      It works on cross-axis. Same values as justify-content. Applied on container.
```
