

```

/*
    To change style using CSS you can use either of three methods:
    1. Using Tags
        The problems with tag is every tags style will change. It is not
specific.
        Meaning, if you select h1 tag then property of every h1 present in the
site will change,
        which we don't want.

    2. Using Class
        We can provide different tags, different class name and can change
style.
        The property of tags only with the class's name will change.

    3. Using ID
        Works similar to classes but there can be only one id with the same name
present in
        whole page alike classes which can be present more than once.

        ID > Class > Tag
*/

/*
    1. We use classes when we need to apply the same style to a group of related
items
    2. We use ID when we need to specific style to a single element on our web
page
    3. More than one classes can be defined in a single HTML element
    4. More than one ID cannot be defined in a single HTML element
    5. IDs and Classes overwrite tag selector
    6. IDs are rarely used
    7. A pseudo-class is used to define a special state of an element. It starts
with colon For eg. a:visited
        For example, it can be used to:
            Style an element when a user mouses over it
            Style visited and unvisited links differently
            Style an element when it gets focus
*/

```
